Note : Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).

Description**BACKGROUND OF THE INVENTION**

5 1. Field of the invention:

This invention relates to a facsimile apparatus for receiving image signals from another facsimile apparatus and forming images corresponding to the received image signals, on image receiving sheets such as paper sheets.

10

2. Description of the prior art:

When transmitting images formed on several paper sheets from a facsimile apparatus (sending apparatus) to another facsimile apparatus (receiving apparatus), each of the original sheets are optically scanned one by one so that the images are transformed into electrical signals (image signals) each representing the pixels of the images, and a connection between the two apparatuses is established via a transmission line (hereinafter, communication established by such a connection is referred to as "a unit of communication"). Then, the image signals are transmitted from the sending apparatus to the receiving apparatus. In the receiving apparatus, the transmitted image signals are converted to the images printed on the same number of image receiving sheets or paper sheets. Usually, as shown in Figure 5, additional data such as a page number PN and the sender's name (as in US-A-4 811 111) or facsimile number are marked at the top of each paper sheet P in accordance with the CCITT recommendation. When another unit of communication is performed between the receiving apparatus and the same or other sending apparatus, another set of paper sheets P for the other unit of communication are output from the receiving apparatus.

The used of such a facsimile apparatus is rapidly increasing in offices, shops or the like. Accordingly, the number of paper sheets P output from a facsimile apparatus used in one place is expanded, and there are chances that paper sheets P of different units of communication may intermix in the course of handling the paper sheets or when they happen to drop from a tray of the apparatus and are scattered on a floor. In such a case, the problem is that the page numbers PN printed on paper sheets P cannot be utilized in rearranging in order the paper sheets of each unit of communication, because the page numbers PN are not given consecutively for all units of communication but for each unit of communication. Usually, paper sheets P are identified according to the sender's name or facsimile number printed at the top. Such a practice involves inefficient and bothersome work, and may often cause wrong recognition of some paper sheets, thereby making the subsequent handling of paper sheets difficult.

35

SUMMARY OF THE INVENTION

A facsimile apparatus according to one aspect of the present invention, which may overcome the above-discussed and numerous other disadvantages and deficiencies of the prior art, has a signal receiving unit for receiving image signals from other facsimile apparatuses after the completion of connection between said apparatus and one of said other facsimile apparatuses, and an image forming unit for forming images on an image receiving sheet, said images corresponding to said received image signals; said apparatus being characterized by: a counting means for counting a running number of connections between said apparatus and other facsimile apparatuses, an index signal generating means for generating an index signal which represents an index mark, and an index mark position-adjusting means for determining the position of the index mark to be formed on an image receiving sheet in accordance with said number of connections; and in that said image forming unit is arranged to form the index mark corresponding to said index signal on each image receiving sheet associated with said running number of connections, at the position determined by said index mark position-adjusting means.

In a preferred embodiment, the index mark position-adjusting means determines one from a predetermined plurality of positions as said determined position.

A facsimile apparatus according to another aspect of this invention has a signal receiving unit for receiving image signals from other facsimile apparatuses after the completion of connection between said apparatus and one of said other facsimile apparatuses, and an image forming unit for forming images on an image receiving sheet, said images corresponding to said received image signals, said apparatus being characterized by: a counting means for counting a running number of connections between said apparatus and other facsimile apparatuses; and an index signal generating means for generating a plurality of index signals which represent a respective plurality of index marks different from each other, one of the index signals being selected

in accordance with said number of connections; and in that said image forming unit is arranged to form the index mark corresponding to said selected index signal on each image receiving sheet associated with said running number of connections.

In a preferred embodiment, said image forming unit is arranged to form said index mark at a predetermined position of said image receiving sheet.

According to another aspect of the invention, there is provided a facsimile apparatus which is operable to perform image recording on one or more image sheets in accordance with image signals received by the apparatus in an image transmission from another apparatus, said facsimile apparatus being arranged to print on the or each image sheet an index mark which visually distinguishes said image sheet or sheets from the image sheet or sheets produced in other different transmissions, the same index mark being recorded on each image sheet in a given transmission, and said facsimile apparatus including means for providing a count of the successive transmissions and means for determining the index mark to be printed in accordance with said count.

Thus, the invention described herein may make possible the objectives of:

- (1) providing a facsimile apparatus which can output image receiving sheets in such a manner that they can be easily, promptly and accurately classified into units of communication even when they are mixed with each other; and
- (2) providing a facsimile apparatus which can output image receiving sheets bearing an index mark which identifies the unit of communication.

BRIEF DESCRIPTION OF THE DRAWINGS

This invention may be better understood and its numerous advantages will become apparent to those skilled in the art by reference to the accompanying drawings as follows:

Figure 1 is a block diagram illustrating an apparatus according to the invention.

Figures 2A and 2B are flow charts illustrating the operation of the apparatus of Figure 1.

Figures 3A and 3B show paper sheets output by the apparatus of Figure 1.

Figures 4A and 4B show paper sheets output by another apparatus according to the invention.

Figure 5 shows paper sheets output by a conventional apparatus.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

Figure 1 shows diagrammatically a facsimile apparatus according to the invention. The apparatus of Figure 1 comprises a CPU 1, a ROM 2, a RAM 3, a printer 4 for forming images on paper sheets, a scanner 5 for reading images from an original, an index generator 6, and a modem 7 which are connected to each other through a bus 10. In accordance with a program stored in the ROM 2, the CPU 1 controls an image forming unit including the printer 4 and scanner 5, and also other components. The modem 7 modulates and demodulates image signals, and is connected to a public telephone communication line 9 via a network control unit 8. The RAM 3 stores received image signals and an accumulated number of units of communication (hereinafter, such a number is referred to as "a communication number").

The index generator 6 has a memory in which an index mark to be printed on a paper sheet is stored. In this embodiment, the index mark is a relatively thick rectangular pattern, printed on the right edge portion of a paper sheet P and at one of five positions M1 - M5 as shown in Figure 3A. The positions M1 - M5 are arranged in a row and at regular intervals. The first position M1 is closest to the top of the paper sheet P, but separated therefrom by a predetermined distance. In accordance with the communication number stored in the RAM 3, the CPU 1 selects one of the positions M1 - M5. When the communication number is $5n$ (where $n = 0, 1, 2, \dots$), the first position M1 is selected. Similarly, when the communication number is $5n + 1$, $5n + 2$, $5n + 3$, or $5n + 4$, the position M2, M3, M4, or M5 is respectively selected. This relationship between the communication numbers and the positions M1 - M5 is summarized in the following Table 1.

Table 1

	<u>Communication number</u>	<u>Position</u>
5	$5n$	M1
	$5n + 1$	M2
	$5n + 2$	M3
10	$5n + 3$	M4
	$5n + 4$	M5

The operation of the facsimile apparatus of Figure 1 will be described with reference to Figures 2A and 2B. The apparatus waits for a ringing signal from another facsimile apparatus (step S1). When receiving a ringing signal, the CPU 1 reads the RAM 3 to read the communication number stored therein (step S2). In accordance with the communication number, one of the positions M1 - M5 is selected (e.g., the position M1) (step S3). Each of the positions M1 - M5 may correspond to a plurality of scanning lines. In step S4, the communication mode (e.g., GII or GIII) is set. Step S5 checks whether a paper sheet exists or not. If not, the process jumps to step S16 after displaying an error message. When a paper sheet exists, image signals for the first page are transmitted from the sending apparatus, and temporarily stored in the RAM 3 (step S6). The image signals for one scanning line which are stored in the RAM 3 are read, and the images corresponding to the signals are printed on the paper sheet by the printer 4 (step S7).

If the index mark position which has been selected in step S3 is not in the present scanning line (hereinafter "the present line"), the process jumps from step S8 to step S12, and repeats steps S6 - S8 and S12 to print images of this page line by line on the paper sheet in the usual manner (i.e., the present line proceeds gradually from the top of the paper sheet to the bottom thereof). When the index mark position starts to exist in the present line, steps S9 - S11 are executed. In step S9, the index mark stored in the index generator 6 is read, and in step S10 the logical OR between the image signals of the present line and the index mark is carried out to obtain composite image signals bearing the index mark. The images of the present line obtained from the composite image signals are printed on the paper sheet (step S10). When the communication number is zero (i.e., $5n$ ($n = 0$)), for example, the index mark is printed at the position M1 as shown in Figure 3A. If there exist images in the lines following the present line, the process returns from step 12 to step S6, and repeats the steps of printing images until all images for the first page are printed.

When the printing procedure of the first page has been completed, the process proceeds to step S13 to check if the printed page is the last page (or the EOP (End of Procedure) signal is received). If the EOP signal is not received (or the MPS (Multi-Page Signal) or EOM (End of Message) signal is received), the process returns to step S5 or step S4 through step S14, and the printing procedure of the succeeding page(s) is repeated until the EOP signal is received. In the example shown in Figure 3A, second and third pages are printed.

When the EOP signal has been received in step S13, the process checks if a DCN (Disconnect) signal is transmitted or not (step S15). If not, the process proceeds to step S16 after displaying an error message. If the DCN signal is transmitted, the process proceeds directly to step S16 wherein the communication number is incremented by one (i.e., the communication number becomes one). This incremented number is stored in the RAM 3 to update the communication number (step S17), and the process for this unit of communication is completed. As a result of the above-described process, three paper sheets P are output. Each of these three paper sheets P bears the index mark at the same position thereof (i.e., at the first position M1) as shown in Figure 3A.

Figure 3B shows paper sheets P obtained in the fourth unit of communication (i.e., the communication number is three ($5n + 3$)). In this case, the index mark is printed at the fourth position M4 on each of the paper sheets P. Even when the paper sheets P of Figure 3A and those of Figure 3B are intermixed with each other, therefore, it is possible to accurately and easily distinguish the former from the latter simply by classifying the paper sheets P in accordance with the position of the index mark.

Figures 4A and 4B show paper sheets P which are output respectively in first and fourth units of communication by another apparatus according to the invention. The paper sheets P obtained in the first unit of communication have an identical index mark m1 which consists of one short bar, and those obtained in the fourth unit of communication have another identical index mark m4 which consists of four short bars. In this embodiment, the index generator 6 holds five kinds of index mark patterns which consist of one to five short bars, respectively, and one of these index patterns is selected according to the communication number. The selected

index pattern is printed as an index mark at substantially the same position of paper sheets P.

According to the invention, the pattern of the index mark and the position of the index mark are not restricted to those above-described, but can be suitably selected.

5

Claims

1. A facsimile apparatus having a signal receiving unit (1,3,8,9) for receiving image signals from other facsimile apparatuses after the completion of connection between said apparatus and one of said other facsimile apparatuses, and an image forming unit (4) for forming images on an image receiving sheet, said images corresponding to said received image signals;
 said apparatus being characterized by:
 a counting means (1,3) for counting a running number of connections between said apparatus and other facsimile apparatuses,
 an index signal generating means (6) for generating an index signal which represents an index mark, and
 an index mark position-adjusting means (1,3) for determining the position of the index mark to be formed on an image receiving sheet in accordance with said number of connections; and in that
 said image forming unit (4) is arranged to form the index mark corresponding to said index signal on each image receiving sheet associated with said running number of connections, at the position determined by said index mark position-adjusting means.
2. A facsimile apparatus according to claim 1, wherein said index mark position-adjusting means is arranged to determine one from a predetermined plurality of positions as said determined position.
3. A facsimile apparatus having a signal receiving unit (1,3,8,9) for receiving image signals from other facsimile apparatuses after the completion of connection between said apparatus and one of said other facsimile apparatuses, and an image forming unit (4) for forming images on an image receiving sheet, said images corresponding to said received image signals,
 said apparatus being characterized by:
 a counting means (1,3) for counting a running number of connections between said apparatus and other facsimile apparatuses; and
 an index signal generating means (6) for generating a plurality of index signals which represent a respective plurality of index marks different from each other, one of the index signals being selected in accordance with said number of connections; and in that said image forming unit (4) is arranged to form the index mark corresponding to said selected index signal on each image receiving sheet associated with said running number of connections.
4. A facsimile apparatus according to claim 3, wherein said image forming unit (4) is arranged to form said index mark at a predetermined position of said image receiving sheet.
5. A facsimile apparatus which is operable to perform image recording on one or more image sheets in accordance with image signals received by the apparatus in an image transmission from another apparatus, said facsimile apparatus being arranged to print on the or each image sheet an index mark which visually distinguishes said image sheet or sheets from the image sheet or sheets produced in other, different transmissions, the same index mark being recorded on each image sheet in a given transmission, and said facsimile apparatus including means (1,3) for providing a count of the successive transmissions and means for determining the index mark to be printed in accordance with said count.

50

Patentansprüche

1. Faksimilegerät mit einer Signalempfangseinheit (1, 3, 8, 9) zum Empfangen von Bildsignalen von anderen Faksimilegeräten nach dem Erstellen einer Verbindung zwischen dem Gerät und einem der anderen Faksimilegeräte, und mit einer Bilderzeugungseinheit (4) zum Erzeugen von Bildern auf einem bildaufnehmenden Blatt, die den empfangenen Bildsignalen entsprechen; **gekennzeichnet durch:**
 - eine Zähleinrichtung (1, 3) zum Zählen der laufenden Nummer von Verbindungen zwischen dem Gerät und anderen Faksimilegeräten;

- eine Indexsignal-Erzeugungseinrichtung (6) zum Erzeugen eines Indexsignals, das eine Indexmarkierung repräsentiert; und
 - eine Indexmarkierungsposition-Einstelleinrichtung (1, 3) zum Festlegen der Position einer auf einem bildaufnehmenden Blatt auszubildenden Indexmarkierung abhängig von der Verbindungsnummer;
 - wobei die Bilderzeugungseinheit (4) so ausgebildet ist, daß sie die Indexmarkierung entsprechend dem Indexsignal auf jedem bildaufnehmenden Blatt erzeugt, das der laufenden Verbindungsnummer zugeordnet ist, und zwar an einer Position, wie sie durch die Indexmarkierungsposition-Einstelleinrichtung festgelegt wird.
2. Faksimilegerät nach Anspruch 1, bei dem die Indexmarkierungsposition-Einstelleinrichtung so ausgebildet ist, daß sie eine aus mehreren vorgegebenen Positionen als festgelegte Position bestimmt.
3. Faksimilegerät mit einer Signalempfangseinheit (1, 3, 8, 9) zum Empfangen von Bildsignalen von anderen Faksimilegeräten nach dem Erstellen einer Verbindung zwischen dem Gerät und einem der anderen Faksimilegeräte, und mit einer Bilderzeugungseinheit (4) zum Erzeugen von Bildern auf einem bildaufnehmenden Blatt, die den empfangenen Bildsignalen entsprechen; **gekennzeichnet durch:**
- eine Zähleinrichtung (1, 3) zum Zählen der laufenden Nummer von Verbindungen zwischen dem Gerät und anderen Faksimilegeräten; und
 - eine Indexsignal-Erzeugungseinrichtung (6) zum Erzeugen mehrerer Indexsignale, die jeweils mehrere voneinander verschiedene Indexmarkierungen repräsentieren, wobei eines der Indexsignale abhängig von der Verbindungsnummer ausgewählt wird;
 - wobei die Bilderzeugungseinheit (4) so ausgebildet ist, daß sie die Indexmarkierung entsprechend dem ausgewählten Indexsignal auf jedem bildaufnehmenden Blatt erzeugt, das der laufenden Verbindungsnummer zugeordnet ist.
4. Faksimilegerät nach Anspruch 3, bei dem die Bilderzeugungseinheit (4) so ausgebildet ist, daß sie die Indexmarkierung an einer vorgegebenen Position des bildaufnehmenden Blatts erzeugt.
5. Faksimilegerät, das so betreibbar ist, daß es Bildaufzeichnung auf einem Bildblatt oder mehreren abhängig von Bildsignalen ausführt, wie sie vom Gerät bei einer Bildübertragung von einem anderen Gerät empfangen werden, wobei das Faksimilegerät so ausgebildet ist, daß es auf das Bildblatt oder jedes Bildblatt eine Indexmarkierung druckt, die das Bildblatt oder die Blätter optisch vom Bildblatt oder den Blättern unterscheidet, wie sie bei anderen, verschiedenen Übertragungen erzeugt werden, wobei auf jedem Bildblatt bei einer vorgegebenen Übertragung dieselbe Indexmarkierung aufgezeichnet wird, und das eine Einrichtung (1, 3) zum Erstellen eines Zählwerts für aufeinanderfolgende Übertragungen und eine Einrichtung zum Bestimmen der zu druckenden Indexmarkierung abhängig vom Zählwert aufweist.

Revendications

1. Appareil de télécopie comportant une unité de réception de signaux (1, 3, 8, 9) pour recevoir des signaux d'images en provenance d'autres appareils de télécopie, une fois que la connexion entre ledit appareil et l'un desdits autres appareils de télécopie a été établie, et une unité de formation d'images (4) pour former des images sur une feuille de réception d'images, lesdites images correspondant auxdits signaux d'images reçus; ledit appareil étant caractérisé par:
- un moyen de comptage (1, 3) pour compter un nombre cumulé de connexions entre ledit appareil et d'autres appareils de télécopie,
 - un moyen de génération de signal d'index (6) pour générer un signal d'index qui représente un repère d'index, et
 - un moyen de réglage de position de repère d'index (1, 3) pour déterminer la position d'un repère d'index à former sur une feuille de réception d'images en fonction dudit nombre de connexions; et en ce que
- ladite unité de formation d'images (4) est conçue pour former le repère d'index correspondant audit signal d'index sur chaque feuille de réception d'images associée audit nombre cumulé de connexions, au niveau de la position déterminée par ledit moyen de réglage de position de repère d'index.
2. Appareil de télécopie selon la revendication 1, dans lequel ledit moyen de réglage de position de repère d'index est conçu pour déterminer, en tant que dite position déterminée, une position parmi une multiplicité

prédéterminée de positions.

3. Appareil de télécopie comportant une unité de réception de signaux (1, 3, 8, 9) pour recevoir des signaux d'images en provenance d'autres appareils de télécopie, une fois que la connexion entre ledit appareil et l'un desdits autres appareils de télécopie a été établie, et une unité de formation d'images (4) pour former des images sur une feuille de réception d'images, lesdites images correspondant auxdits signaux d'images reçus,
 ledit appareil étant caractérisé par:
 un moyen de comptage (1, 3) pour compter un nombre cumulé de connexions entre ledit appareil et d'autres appareils de télécopie; et
 un moyen de génération de signal d'index (6) pour générer une multiplicité de signaux d'index qui représentent une multiplicité respective de repères d'index différents les uns des autres, l'un des signaux d'index étant sélectionné en fonction dudit nombre de connexions; et en ce que ladite unité de formation d'images (4) est conçue pour former le repère d'index correspondant audit signal d'index sélectionné sur chaque feuille de réception d'images associée audit nombre cumulé de connexions.
4. Appareil de télécopie selon la revendication 3, dans lequel ladite unité de formation d'images (4) est conçue pour former ledit repère d'index au niveau d'une position prédéterminée de ladite feuille de réception d'images.
5. Appareil de télécopie qui est apte à effectuer un enregistrement d'images sur une ou plusieurs feuilles d'images en fonction de signaux d'images reçus par l'appareil lors d'une transmission d'images effectuée à partir d'un autre appareil, ledit appareil de télécopie étant conçu pour imprimer sur la, ou sur chaque, feuille d'images un repère d'index qui permet d'établir une distinction visuelle entre ladite ou lesdites feuille(s) d'images et la ou les feuille(s) d'images produites lors d'autres transmissions différentes, le même repère d'index étant enregistré sur chaque feuille d'images lors d'une transmission donnée, et ledit appareil de télécopie comprenant des moyens (1, 3) pour fournir un comptage des transmissions successives et des moyens pour déterminer le repère d'index à imprimer en fonction dudit comptage.
